BCHM 463  
Biochemistry and Physiology  
Exam II, November 4, 2002  
Prof. Jason Kahn

You have 50 minutes for this exam.  
Exams written in pencil or erasable ink will not be re-graded under any circumstances. 
You may use a calculator for this exam. No other study aids or materials are permitted. 
Generous partial credit will be given, i.e., if you don’t know, guess. 
Explanations should be concise and clear. 

Honor Pledge: Please write out the following sentence and sign it, or talk to me about it: 
“I pledge on my honor that I have not given or received any unauthorized assistance on this examination.”

Possibly useful information: 

Michaelis-Menten equation: $v_0 = V_{max}(S)/(K_M + [S])$

<table>

</tbody>
</table>

$\alpha = 1 + ([I]/K_I)$  
$\alpha' = 1 + ([I]/K_{I'})$

$V_{max} = k_{cat} [E]_{total}$

RT = 2476 J/mole today

$\Delta G = \Delta G^{\circ} + RT \ln Q$, where Q has the form of an equilibrium constant

$\Delta G = -nFE$, where F = 96500 J/(V•mole), n = number of electrons transferred

$\Delta G^{\circ} = -30.5 \text{kJ/mole for } AT^4 + H_2O \rightleftarrows ADP^3^- + HPO_4^{2-} + H^+$
1. **Michaelis-Menten Kinetics (25 pts):**

A schematic graph of Michaelis-Menten kinetics in the presence of an inhibitor is shown below. The lines are drawn through experimental data (not shown) in the absence of inhibitor and at increasing inhibitor concentration, as indicated by the curved arrow.

The lines here intersect at point B, representing mixed inhibition, but in general they could intersect at any point from A to E. Point E, at infinity in the indicated direction, represents pure competitive inhibition.

(a; 7 pts) If the lines had intersected at point A instead, discuss what this would have meant in terms of what you observe as you add more and more substrate to the reaction at different inhibitor concentrations. What kind of inhibition would intersection at A represent?

The y-axis refers to infinite substrate concentration. Intersection at A would mean that at infinite substrate concentration all reactions reach the same level, that inhibitor is swamped out. This represents **competitive inhibition**.

(b; 6 pts) What two types of inhibition are being mixed to give mixed inhibition? Why do we consider non-competitive inhibition to be a special case of mixed?

Mixed is a mixture of competitive and uncompetitive. (+1 for either, +3 for both)

- B - C - D are all mixed - non-competitive is the special case where $K_m$ is unaffected, whereas in general for a mixed inhibitor, $K_m$ can be up or down. In other words, mixed represents intersection somewhere between A and B, and C is just the special case of unaffected $K_m$. 

---

(58)
(c; 7 pts) In which quadrant do all of the experimental data points lie? Why can’t the lines ever intersect in Quadrant I (Q1) for a simple M-M enzyme? Why can’t they intersect in Q4?

4. All in Q1 - 4 N₀, 4 [S]
4. Can’t intersect in Q1 because that would mean that for some [S] the velocity would be greater for the inhibited reaction.
4. Can’t intersect in Q4 because the lines can never cross Q4! That would correspond to a Q N₀ for a real [S].

(d; 5 pts) What is the appropriate measure of quality for an enzyme, and what is the physical process that limits the performance of enzymes (answer is about 16 characters)?

3. Largest Km (or any variant)
2. Diffusion

2. Glycolysis (23 pts):

(a; 10 pts) The story so far of glycolysis is sketched below. Indicate the two steps that are strongly favorable energetically, and name the enzymes that catalyze these steps. We identified one of these steps as the crucial control point for glycolysis (at least among the reactions we have studied so far). Which one is it, and what is the chemical equation (write out chemical names for the glycolytic intermediates) for the reaction it catalyzes?

Pentose phosphate pathway

Glucose → G6P → F6P → GAP+DHAP

Glycogen

PGI

Fructose-6-phosphate + ATP → fructose-1,6-bisphosphate + ADP

4 +1 if there are any errors, +1 if no ATP

5 +1 if there are any errors, +1 if no ATP
(b; 8 pts) Explain why a step which is roughly at equilibrium is not a good candidate for regulation, couching your answer in terms of flux control. Also, give one reason why the other thermodynamically favorable step in (a) is not as highly regulated as the one you identified.

A → B → C → D

13. For the idea
As Kp that is of equilibrium has → and → flux. Therefore, reducing the possible flux requires a very high demand on the enzymatic activity. Don’t put a dam in the middle of a lake.

Flux is constant through a pathway!

The reaction reaction is not as highly regulated because
1. It’s not a committed step for glycolysis – there are other sources of G6P and other ways for it

2. Either 2. Presumably it is advantageous to glycolylate it; return glucose even if there is no current need for it.

(c; 5 pts) Draw D-glyceraldehyde-3-phosphate (GAP) and indicate the stereocenter that would be inverted to give L-glyceraldehyde-3-phosphate.
3. Enzymatic Catalysis (22 pts):

(a) 7 pts) Draw the mechanism for the base-catalyzed formation of a Schiff's base between lysine and acetone. You may represent the protonated form of lysine as RNH₂⁺. Where have we seen something like this in glycolysis?

(b) 12 pts) One intermediate in the phosphoglucone isomerase (PGI) reaction mechanism is shown below. Draw the arrow-pushing and intermediates for the next two steps toward fructose. Lysine is not involved. [Protonation of an enediolate does not count as a step.]

[Diagram showing the enzymatic catalysis process with various chemical structures and reactions described.]
(c; 3 pts) What kind of catalysis and what type of reaction does the mechanism in (b) represent?

4. Bioenergetics and Baseball (30 pts):

Creatine supplementation is used by athletes to enhance their muscles' ability to sustain maximal exertion, as in weight lifting and home run hitting. Supplementation can increase creatine concentration in the muscle by 30% or so, to a total body burden of about 150 g (MW is 121). [Creatine has the added advantages of being legal and also relatively safe.] Creatine phosphate is a "high-energy" molecule, i.e. it has a large negative standard free energy for phosphate hydrolysis ($\Delta G^\circ = -43.1$ kJ/mol). Its structure is shown below.

(a; 9 pts) Draw a resonance form for creatine phosphate that illustrating one reason why it is "high-energy," and state what reason it illustrates. Name one other driving force that we discussed that contributes to highly exergonic bond hydrolysis in general.
The creatine phosphate hydrolysis products at pH 7 are creatine (below) and P_i:

(b: 6 pts) Creatine phosphate hydrolysis can be used to drive the synthesis of ATP from ADP and P_i (though P_i would not actually be a free intermediate in the reaction). Write down the chemical equations for creatine phosphate hydrolysis, ATP hydrolysis in the appropriate direction, and the net chemical equation for the coupled reactions. Calculate ΔG°' given that the ΔG°' for ATP hydrolysis to give ADP + P_i is -30.5 kJ/mol.

1. \[ \text{creatinine} - (\text{\textcircled{3}}) + \text{H}_2\text{O} \rightarrow \text{creatinine} + \text{P}_i \quad \Delta G^\circ = -43.1 \text{ kJ/mol} \]
2. \[ \text{ADP} + \text{P}_i \rightarrow \text{ATP} + \text{H}_2\text{O} \quad \Delta G^\circ = +30.5 \text{ kJ/mol} \]
3. \[ \text{creatinine} - (\text{\textcircled{2}}) + \text{ADP} \rightarrow \text{creatinine} + \text{ATP} \quad \Delta G^\circ = -12.6 \text{ kJ/mol} \]

(c: 6 pts) Given the following concentrations, calculate the actual ΔG (at pH 7) for the ATP synthesis reaction above. Creatine phosphate = 60 mM, creatine = 30 mM, ATP = 1 mM, ADP = 0.1 mM.

\[ \Delta G = \Delta G^\circ + R \ln \frac{[\text{creatinine}][\text{ATP}]}{[\text{creatinine}][\text{ADP}]} \]

\[ = -12.6 \text{ kJ/mol} + 2.476 \text{ kJ/mol} \ln \left( \frac{(60)(1)}{(60)(0.1)} \right) \]

\[ = \boxed{-8.6} \]
(d; 9 pts) Why don’t athletes use the "high-energy" creatine phosphate instead? Answer in terms of thermodynamics, assuming that a 30 g Snickers bar can considered to be all glucose (MW = 180), and that aerobic metabolism of glucose provides approximately 38 moles of ATP (from ADP) per mole of glucose. Your calculations need not be exact.

$$\frac{30 \text{ g glucose}}{180 \text{ g/mole}} \times \frac{1}{6} \text{ mole ATP} \times 38 \text{ = 6 mole ATP synthesized}$$

There's only ~1.25 moles of creatine in the body and the supplement is ~0.25 mole.

True the additional energy in creatine phosphate is trivial relative to normal intake. It's the added anaerobic capacity that's desirable.

89/80 for idea with no calculations
