Exam I (100 points total)		March 7, 2011

You have 50 minutes for this exam.

Exams written in pencil or erasable ink will not be re-graded under any circumstances.

Explanations should be <u>concise</u> and <u>clear</u>. I have given you more space than you should need. There is extra space on the last page if you need it.

You will need a calculator for this exam. No other study aids or materials are permitted.

Partial credit will be given, *i.e.*, if you don't know, guess.

**Useful Equations:** 

$K_a = [\mathrm{H}^+][\mathrm{A}^-]/[\mathrm{H}\mathrm{A}]$	$pH = -log([H^+])$	$K_b = [BH^+][HO^-]/[B]$
F = ma	$e^{i\pi} + 1 = 0$	PV = nRT
$K_w = [\mathrm{H}^+][\mathrm{HO}^-] = 10^{-14}$	$pH = pK_a + \log([A^-]/[HA])$	pH (e.p.) = $(pK_{a1} + pK_{a2})/2$
$R = 0.08206 \text{ L} \cdot \text{atm/mole K}$	0 °C = 273.15 K	$pK_a = -\log(K_a)$
$K_p = K_c(\mathrm{RT})^{\Delta n}$	$P^2/a^3 = 4\pi^2/MG$	$\nabla \times E = -\partial B / \partial t$

Honor Pledge: At the end of the examination time, please write out the following sentence and sign it, or talk to me about it:

"I pledge on my honor that I have not given or received any unauthorized assistance on this examination."

+1 point extra credit for filling in this box

## **<u>1.</u>** (20 pts) Fill in the Blanks

Read the whole sentence before you fill in the blanks.

(a; 2 pts) $K_c$ and $K_p$ are equal if the	does not
change during the reaction.	
(b; 2 pts) The value of the reaction quotient <i>Q</i> approaches	
as the reaction progresses.	
(c; 4 pts) At equilibrium, the rates of forward and reverse reactions are	
and areas each	ı other.
(d; 4 pts) The	
of a weak acid is a strong base whose $pK_b$ can be predicted from the $pK_a$ of the weak	acid using the
equation	
(e; 2 pts) $K_w$ is the equilibrium constant for the	
(f; 2 pts) The concentration of a solid or a pure liquid is constant as long as some of it is s	still present, so it is
the reaction quotient express	ion.
(g; 4 pts) Ideal gases are defined by two properties: the particles have no	

volume and they \_\_\_\_\_\_attract each other.

## 2. (28 pts) Chemical Equilibria [Adapted from Oxtoby].

(a; 18 pts) Explain the effect of each of the following stresses on the position of the following equilibrium:

$$3 \text{ NO}(g) \rightleftharpoons N_2 O(g) + NO_2(g)$$

The reaction as written is exothermic (releases heat). In each case, briefly explain which way the equilibrium shifts and explain why. The five cases are independent of each other.

- (i)  $N_2O(g)$  is added to a mixture at equilibrium without changing the volume or the temperature.
- (ii) The volume of the equilibrium mixture is reduced at constant temperature.
- (iii) The equilibrium mixture is cooled at constant volume.

Questions (iv) and (v) are frequently answered incorrectly. Hint: Think about the Q and its ingredients.

(iv) Gaseous argon (which does not react) is added to the equilibrium mixture and the <u>total</u> gas pressure and the temperature are maintained constant. (Hint: how would this be done?)

(v) Gaseous argon is added to the equilibrium mixture <u>without</u> changing the volume or temperature. (Hint: what will the effect on Q be?)

At equilibrium at 425.6 °C, a sample of *cis*-1-methyl-2-ethylcyclopropane is 73.6 % converted to the *trans* form (i.e. 73.6 % of the material is found in the *trans* form at equilibrium):

(b; 4 pts) Compute the equilibrium constant K for this reaction at 425.6 °C.

(c; 6 pts) Suppose that 0.525 mol of the *cis* compound is initially placed in a 15.0 L vessel and is then heated to 425.6 °C. Compute the equilibrium partial pressure of the *cis* and *trans* compounds. [Hint: you don't actually need the answer to part (a) to solve this.]

## 3. (22 pts) Acid-base equilibria

Consider four separate titrations of a weak acid HA  $(pK_a = 3.7)$  with four different weak bases B2, B4, B6, and B8, with  $pK_b$ 's = 2, 4, 6, and 8 respectively.

The family of titration curves is shown in the graph at the right. The total concentration of acid is 0.1 M and the final concentration of base is 0.2 M. Ignore dilution.

(a; 6 pts) What is the dominant reaction occurring in the solution as HA and B are mixed?

Explain why all the titration curves look the same on the left half of the graph.

(b; 6 pts) When the final total concentrations of acid and base are 0.1 M and 0.2 M respectively, what are the concentrations [B] and [BH<sup>+</sup>], approximately (no ICE tables!). Using the base dissociation equilibrium, justify the circled pH values on the right hand side of the graph: show the calculation only once since it is the same for all of them.

(c; 10 pts) The exact calculation of the titration curve of HA with B is complicated, especially at low concentrations of HA and B. We would like to solve for the six concentrations [HA], [A<sup>-</sup>], [B], [BH<sup>+</sup>], [H<sup>+</sup>], and [HO<sup>-</sup>] given the K<sub>a</sub> for HA, the K<sub>b</sub> for B, and the input concentrations CA and CB. Write down the six equations that we would need to solve for the six variables.

## 3. (30 pts) Hemoglobin and Linkage

- The molecule 2,3-bisphosphoglycerate (2,3-BPG) controls short-term adaptation to high altitude. It binds to T-state hemoglobin about 250-fold more tightly than it does to R-state hemoglobin. We know that the R and T states also interconvert.
- (a; 8 pts) Given the three equilibria below, provide a linkage argument to show that the equilibrium constant for the interconversion of R•BPG and T•BPG is 25000.

 $R \bullet BPG \rightleftharpoons R + BPG \qquad K_{diss,R} = 3.0 \times 10^{-3} \text{ M} \qquad R \rightleftharpoons T \qquad K_{RT} = 100$  $T \bullet BPG \rightleftharpoons T + BPG \qquad K_{diss,T} = 1.2 \times 10^{-5} \text{ M} \qquad R \bullet BPG \rightleftharpoons T \bullet BPG \qquad K_{RTBPG} = ?$ Show that  $K_{RTBPG} = 25000$ :

(b; 12 pts) The mathematics of linkage is complicated. We will consider simplified cases and ignore the fact that Hb binds 4 (not 1) molecules of O<sub>2</sub>. First, consider oxygen binding in the absence of BPG. The R state binds O<sub>2</sub> about 100 times better than the T state:

$R \bullet O_2 \rightleftharpoons R + O_2$	$K_{0,R} = 1.3 \times 10^{-4}$ atm	(this is a dissociation equilibrium)
$T \bullet O_2 \rightleftharpoons T + O_2$	$K_{0,T} = 1.3 \times 10^{-2}$ atm	(this is a dissociation equilibrium)
$R \rightleftharpoons T$	$K_{RT} = 100$	

If we find in the end that  $[R] = 1.5 \mu M$  and  $[O_2] = 2.6 \times 10^{-2}$  atm (assumed constant) use the equilibria above to give the concentrations of R•O<sub>2</sub>, T, and T•O<sub>2</sub>. The calculation is very straightforward: since I give you the equilibrium concentrations of R and O<sub>2</sub> you do not need an ICE table.

Calculate the fraction of the total hemoglobin that is bound to oxygen, i.e. calculate  $([R \bullet O_2]+[T \bullet O_2])/([R \bullet O_2]+[T \bullet O_2]+[R]+[T])$ .

(c; 10 pts) Next will consider the case when [BPG] is present, at high enough concentration so that all of the hemoglobin is in the BPG-bound form. We will assess the effect of BPG on oxygen binding. We assume that the dissociation constants for the R and T states are the same with and without BPG.

$R \bullet BPG \bullet O_2 \rightleftharpoons R \bullet BPG + O_2$	$K_{O,R} = 1.3 \times 10^{-4}$ atm	same as before
$T \bullet BPG \bullet O_2 \rightleftharpoons T \bullet BPG + O_2$	$K_{0,T} = 1.3 \times 10^{-2}$ atm	same as before
$R \bullet BPG \rightleftharpoons T \bullet BPG$	$K_{RTBPG}$ = 25000	

Based on LeChatelier, circle whether more or less Hb is bound to  $O_2$  in the presence of BPG versus in its absence. If [R•BPG] = 10 nM and  $[O_2] = 2.6 \times 10^{-2}$  atm (assumed constant) calculate the concentrations of R•BPG•O<sub>2</sub>, T•BPG, and T•BPG•O<sub>2</sub>. What fraction of the total hemoglobin is bound to oxygen?
